Abstract. This paper contains 1062 taxa of dicotyledons, which represent part of the vascular flora of the Uludag. Conclusions on the major threats to plant diversity and possible measures for conservation of the high diversity in that area are presented.

Conclusions

The Uludag is a floristically interesting area, in addition to being one of the most famous centres for winter sports in Turkey. The main causes for damages to plant diversity in the area are as follows: construction of hotels and ski lift areas, excessive human activities such as picnicking, camping, tracking in summer months, overgrazing and overcollection of plants. The most serious problem is the excessive construction aimed at winter tourism, both at the foothills of the mountain and in the First and Second Centres of Tourism Development within the National Park (Daşkın & Kaynak 2005, 2007).

Moreover, most endemic plants are mainly located in the First and Second Centres of Tourism Development, in the Fatin Hill, Şahinkaya, Kuşaklıkaya, around the Tungsten Mine, Rasatdüzü Locality, Lakes District, Kirazlıyayla, Çobankaya, Kırkpınarlar Locality, Sarıalan and between Alaçam and the Lakes District, where in winter and summer tourism activities are very intensive. Thus, during these activities, habitats of the endemic plants have been destroyed and their populations have decreased (Daşkın & Kaynak 2007).

Although the study area is extremely important floristically, it is not sufficiently protected. Therefore, the following measures should be taken for the purposes of conservation of the area:

- i. Legal decisions for the protection and use of the Uludag Mountain should be made promptly by the local government;
- ii. Some legal arrangements could be aimed at the reduction of the number of visitors. For example, picnicking, camping, grazing and unauthorized plant and animal collection could be banned in the National Park;
- iii. Visitors should be allowed entry only with guides. Guides familiar with the plant and animal diversity of the area should be trained;
- iv. The threatened plant taxa must be protected *in situ* and *ex situ*. For *in situ* conservation, short-term measures for protection of the habitats of endangered plants should be taken. The possible long-term measures are as follows:

Visitors should be informed about the biological diversity of the area and its importance. For this purpose, brochures, billboards and handbooks that describe the plant and animal species in the area can be prepared. Recently, a book was brought out with photographs of all endangered plants in the area, their detailed descriptions and information about their habitat (Kaynak & al. 2008).

During the opening of ski trails, some rocks and soils were dislodged. As a result, habitats of some endangered species were damaged and the productivi-

ty of the soils was reduced. To improve these damaged areas, some plants that comprise the characteristic vegetation of these areas, such as *Juniperus communis* var. *saxatilis*, *Daphne oleoides*, *Genista lydia* and *Festuca* species can be planted. Maintenance of these plants will be the first step in the improved processing of these areas.

For *ex situ* conservation, herbarium specimens and seeds of the threatened plants should be collected. During our field studies, we collected herbarium specimens belonging to these taxa. The seeds of some threatened plants were also collected.
